

Combined optical transceiver module

Overview

There have been multiple variants of the electrical interface of optical modules that have been used over the years. The earliest forms of optical modules had an analog NRZ electrical interface. In the transmit direction, the optical module would directly drive the laser or LED with the analog signal coming from the front system card.

Key Takeaways

A combined transceiver optical module integrates both an optical transmitter and receiver in a single unit to enable bidirectional high-speed optical communication.

A combined transceiver optical module is a hot-pluggable device that performs photoelectric conversion for optical communication systems, allowing data to be transmitted and received over fiber optic cables simultaneously. It integrates an optical transmitter (Tx) and an optical receiver (Rx) in one module, providing a complete physical-layer interface between electronic systems and optical networks. This integration simplifies network design, reduces hardware footprint, and supports high-density deployments in data centers and telecom networks.

Structure and Function

The module typically consists of:

- Optoelectronic devices: Semiconductor lasers (LD) or LEDs for transmission and photodiodes for reception.

- Functional circuits: Driver and preamplifier circuits for signal modulation and amplification.
- Optical interfaces: Standardized connectors such as MPO or LC for fiber connectivity . The working principle involves converting electrical signals from network equipment into modulated optical signals for transmission, and then converting incoming optical signals back into electrical signals for processing . This allows seamless bidirectional communication over a single fiber or multiple fibers.

Applications

Combined transceiver modules are widely used in:

- Data centers: High-speed interconnects for AI, machine learning, and hyperscale computing networks .
- Telecom networks: Backbone and metro networks requiring 100 Gb/s to 800 Gb/s per wavelength, often using coherent modulation formats like QPSK or 16-QAM .
- High-performance computing: Low-latency, power-efficient optical links for large-scale computing clusters .

Standards and Performance

These modules adhere to industry standards such as OIF CMIS and XPO Module Specifications, ensuring interoperability and reliability . Modern modules support extremely high data rates, for example, 12.8 Tb/s Ethernet connectivity with 224 Gb/s per lane, and incorporate digital signal processing (DSP) for dispersion and polarization compensation . They are designed for low latency, high efficiency, and high-density deployment, making them suitable for AI and hyperscale data center applications .

Advantages

- Bidirectional communication in a single module reduces cabling complexity.
- High-speed performance supports next-generation Ethernet and optical networks.
- Hot-pluggable design allows easy upgrades and maintenance.
- Compatibility with multiple form factors (QSFP-DD, OSFP, XPO) for flexible deployment . In summary, a combined transceiver optical module is a critical component for modern high-speed optical networks, providing integrated transmission and reception, high data rates, and efficient deployment in data centers and telecom infrastructures.
