

## Operating time limit of relay protection

### Overview

**Upper Limit of Relay Operating Time** This chapter aims to provide some guidelines that should be considered during setting the upper limit of relay operation.

### Key Takeaways

The operating time limit of relay protection is determined by the relay type, time-current characteristics, and coordination with upstream and downstream devices, typically ranging from milliseconds for instantaneous relays to several seconds for time-graded overcurrent relays.

**Key Principles**

Relay operating time is the interval between the occurrence of a fault and the relay initiating a trip signal. It is influenced by:

- **Relay type:** Definite-time relays operate after a fixed delay regardless of fault magnitude, while inverse-time relays operate faster for higher fault currents. Instantaneous relays act almost immediately, typically within milliseconds.
- **Time-current characteristics:** Relays follow curves (standard, very inverse, extremely inverse) that define operating time as a function of fault current magnitude.
- **Coordination and grading:** To ensure selective protection, relays are time-graded so that the relay closest to the fault operates first, with upstream relays delayed by a margin to avoid unnecessary tripping.

**Determining Operating Time**

- **Plug Setting Multiplier (PSM):** Indicates how many times the fault current exceeds the relay pickup current. Higher PSM results in faster operation.

- Time Setting Multiplier (TSM): Scales the base operating time from the relay's characteristic curve to achieve proper coordination with other relays .
- Time margin: Additional delay is added to upstream relays to ensure downstream relays clear the fault first, typically around 0.2-0.5 seconds depending on breaker and relay tolerances .

#### Typical Operating Time Ranges

- Instantaneous relays: 0-0.1 seconds, used for high fault currents.
- Inverse-time overcurrent relays: 0.2-5 seconds depending on fault magnitude and coordination requirements.
- Definite-time relays: Fixed delays, often 0.5-2 seconds for feeder protection.
- Time-graded schemes: Total grading interval between successive relays is usually around 0.4-0.5 seconds to ensure discrimination .

#### Practical Considerations

- The maximum operating time is limited by the need to prevent equipment damage and maintain system stability.
- Multiple-stage protection is often used, with low-set, high-set, and instantaneous stages to balance sensitivity and speed .
- Numerical relays allow precise setting of operating times and coordination with other relays, improving selectivity and reducing unnecessary outages . In summary, the operating time limit of relay protection is a carefully calculated value based on relay characteristics, fault current levels, and coordination requirements, ensuring rapid fault clearance while maintaining selectivity and system reliability.
