

Relay protection consists of three parts

Overview

Electromechanical relays can be classified into several different types as follows: "Armature"-type relays have a pivoted lever supported on a hinge or knife-edge pivot, which carries a moving contact. These relays may work on either alternating or direct current, but for alternating current, a shading coil on the pole is used to maintain contact force throughout the alternating current cycle.

Key Takeaways

The three essential components of relay protection are the sensing element, the relay logic (decision-making unit), and the trip output (actuating device).1. Sensing Element

The sensing element detects abnormal electrical conditions such as overcurrent, overvoltage, underfrequency, or differential currents. This is typically achieved using current transformers (CTs) and potential transformers (PTs), which scale high system voltages and currents to levels suitable for the relay to process. The CTs and PTs provide accurate measurements to the relay, ensuring it can detect faults reliably without directly handling high power .

2. Relay Logic (Decision-Making Unit)

The relay logic is the core of the protective relay. It evaluates the signals from the sensing elements against preset thresholds or algorithms. Depending on the type of relay—electromechanical, static, or numerical—the logic may be mechanical, electronic, or software-based. This component determines whether a fault exists and decides the appropriate action, such as tripping a breaker or issuing an alarm .

3. Trip Output (Actuating Device)

The trip output is the mechanism that executes the relay's decision. When the relay logic identifies a fault, it sends a signal to the circuit breaker or other interrupting device to isolate the faulty section. This prevents equipment damage, maintains system stability, and limits the impact of the fault to the smallest possible area. The trip output may also trigger alarms or initiate other protective functions .

Summary

In essence, relay protection relies on a chain of three components: the sensing element captures system parameters, the relay logic interprets these signals to detect faults, and the trip output isolates the faulted section. Each component is critical; a failure in any link can compromise the protection scheme, highlighting the importance of proper design, coordination, and testing .
